In this section we examine equations of the form $y' = f(y)$, called autonomous equations, where the independent variable $t$ does not appear explicitly.

The main purpose of this section is to learn how geometric methods can be used to obtain qualitative information directly from differential equation without solving it.

Example (Exponential Growth):

$y' = ry$, $r > 0$

Solution:

$y = y_0 e^{rt}$
Logistic Growth

An exponential model \( y' = ry \), with solution \( y = e^{rt} \), predicts unlimited growth, with rate \( r > 0 \) independent of population.

Assuming instead that growth rate depends on population size, replace \( r \) by a function \( h(y) \) to obtain \( y' = h(y)y \).

We want to choose growth rate \( h(y) \) so that
- \( h(y) \equiv r \) when \( y \) is small,
- \( h(y) \) decreases as \( y \) grows larger, and
- \( h(y) < 0 \) when \( y \) is sufficiently large.

The simplest such function is \( h(y) = r - ay \), where \( a > 0 \).

Our differential equation then becomes

\[
y' = (r - ay)y, \quad r, a > 0
\]

This equation is known as the Verhulst, or logistic, equation.
Logistic Equation

The logistic equation from the previous slide is
\[ y' = (r - ay)y, \quad r, a > 0 \]

This equation is often rewritten in the equivalent form
\[ \frac{dy}{dt} = r \left(1 - \frac{y}{K}\right)y, \]

where \( K = r/a \). The constant \( r \) is called the **intrinsic growth rate**, and as we will see, \( K \) represents the **carrying capacity** of the population.

A direction field for the logistic equation with \( r = 1 \) and \( K = 10 \) is given here.
Logistic Equation: Equilibrium Solutions

Our logistic equation is
\[
\frac{dy}{dt} = r \left(1 - \frac{y}{K}\right)y, \quad r, K > 0
\]

Two equilibrium solutions are clearly present:
\[y = \phi_1(t) = 0, \quad y = \phi_2(t) = K\]

In direction field below, with \(r = 1, K = 10\), note behavior of solutions near equilibrium solutions:
\(y = 0\) is unstable,
\(y = 10\) is asymptotically stable.
Autonomous Equations: Equilibrium Solns

Equilibrium solutions of a general first order autonomous equation $y' = f(y)$ can be found by locating roots of $f(y) = 0$.

These roots of $f(y)$ are called critical points.

For example, the critical points of the logistic equation

$$\frac{dy}{dt} = r\left(1 - \frac{y}{K}\right)y$$

are $y = 0$ and $y = K$.

Thus critical points are constant functions (equilibrium solutions) in this setting.
Logistic Equation: Qualitative Analysis and Curve Sketching (1 of 7)

To better understand the nature of solutions to autonomous equations, we start by graphing $f(y)$ vs. $y$.

In the case of logistic growth, that means graphing the following function and analyzing its graph using calculus.

$$f(y) = r \left(1 - \frac{y}{K}\right)y$$
Logistic Equation: Critical Points  (2 of 7)

The intercepts of $f$ occur at $y = 0$ and $y = K$, corresponding to the critical points of logistic equation.

The vertex of the parabola is $(K/2, rK/4)$, as shown below.

\[ f(y) = r \left( 1 - \frac{y}{K} \right) y \]

\[ f'(y) = r \left[ \left( -\frac{1}{K} \right) y + \left( 1 - \frac{y}{K} \right) \right] \]

\[ = -\frac{r}{K} [2y - K] \overset{set}{=} 0 \Rightarrow y = \frac{K}{2} \]

\[ f\left(\frac{K}{2}\right) = r \left( 1 - \frac{K}{2K} \right) \left( \frac{K}{2} \right) = \frac{rK}{4} \]
Logistic Solution: Increasing, Decreasing  (3 of 7)

Note $dy/dt > 0$ for $0 < y < K$, so $y$ is an increasing function of $t$ there (indicate with right arrows along $y$-axis on $0 < y < K$).

Similarly, $y$ is a decreasing function of $t$ for $y > K$ (indicate with left arrows along $y$-axis on $y > K$).

In this context the $y$-axis is often called the phase line.

$$\frac{dy}{dt} = r\left(1 - \frac{y}{K}\right)y, \quad r > 0$$
Logistic Solution: Steepness, Flatness  (4 of 7)

Note \( \frac{dy}{dt} \approx 0 \) when \( y \approx 0 \) or \( y \approx K \), so \( y \) is relatively flat there, and \( y \) gets steep as \( y \) moves away from 0 or \( K \).

\[
\frac{dy}{dt} = r \left( 1 - \frac{y}{K} \right) y
\]
Logistic Solution: Concavity  (5 of 7)

Next, to examine concavity of $y(t)$, we find $y'''$:

$$\frac{dy}{dt} = f(y) \quad \Rightarrow \quad \frac{d^2 y}{dt^2} = f'(y) \frac{dy}{dt} = f'(y)f(y)$$

Thus the graph of $y$ is concave up when $f$ and $f'$ have same sign, which occurs when $0 < y < K/2$ and $y > K$.

The graph of $y$ is concave down when $f$ and $f'$ have opposite signs, which occurs when $K/2 < y < K$.

Inflection point occurs at intersection of $y$ and line $y = K/2$. 

![Graph of Logistic Solution: Concavity](image)
Logistic Solution: Curve Sketching (6 of 7)

- Combining the information on the previous slides, we have:
  - Graph of $y$ increasing when $0 < y < K$.
  - Graph of $y$ decreasing when $y > K$.
  - Slope of $y$ approximately zero when $y \leq 0$ or $y \geq K$.
  - Graph of $y$ concave up when $0 < y < K/2$ and $y > K$.
  - Graph of $y$ concave down when $K/2 < y < K$.
  - Inflection point when $y = K/2$.

- Using this information, we can sketch solution curves $y$ for different initial conditions.
Logistic Solution: Discussion (7 of 7)

Using only the information present in the differential equation and without solving it, we obtained qualitative information about the solution $y$.

For example, we know where the graph of $y$ is the steepest, and hence where $y$ changes most rapidly. Also, $y$ tends asymptotically to the line $y = K$, for large $t$.

The value of $K$ is known as the carrying capacity, or saturation level, for the species.

Note how solution behavior differs from that of exponential equation, and thus the decisive effect of nonlinear term in logistic equation.
Solving the Logistic Equation  (1 of 3)

Provided $y \neq 0$ and $y \neq K$, we can rewrite the logistic ODE:

$$\frac{dy}{(1 - y/K)y} = r dt$$

Expanding the left side using partial fractions,

$$\frac{1}{(1 - y/K)y} = \frac{A}{1 - y/K} + \frac{B}{y} \quad \Rightarrow \quad 1 = Ay + B(1 - y/K) \quad \Rightarrow \quad B = 1, \quad A = y/K$$

Thus the logistic equation can be rewritten as

$$\left(\frac{1}{y} + \frac{1/K}{1 - y/K}\right)dy = r dt$$

Integrating the above result, we obtain

$$\ln|y| - \ln\left|1 - \frac{y}{K}\right| = rt + C$$
Solving the Logistic Equation (2 of 3)

We have:

\[ \ln |y| - \ln \left| 1 - \frac{y}{K} \right| = rt + C \]

If \( 0 < y_0 < K \), then \( 0 < y < K \) and hence

\[ \ln y - \ln \left( 1 - \frac{y}{K} \right) = rt + C \]

Rewriting, using properties of logs:

\[ \ln \left[ \frac{y}{1 - y/K} \right] = rt + C \quad \Rightarrow \quad \frac{y}{1 - y/K} = e^{rt+c} \quad \Rightarrow \quad \frac{y}{1 - y/K} = ce^{rt} \]

or \( y = \frac{y_0 K}{y_0 + (K - y_0)e^{-rt}} \), where \( y_0 = y(0) \)
We have:

\[ y = \frac{y_0 K}{y_0 + (K - y_0)e^{-rt}} \]

for \( 0 < y_0 < K \).

It can be shown that solution is also valid for \( y_0 > K \). Also, this solution contains equilibrium solutions \( y = 0 \) and \( y = K \).

Hence solution to logistic equation is

\[ y = \frac{y_0 K}{y_0 + (K - y_0)e^{-rt}} \]
Logistic Solution: Asymptotic Behavior

The solution to logistic ODE is

$$y = \frac{y_0 K}{y_0 + (K - y_0)e^{-rt}}$$

We use limits to confirm asymptotic behavior of solution:

$$\lim_{t \to \infty} y = \lim_{t \to \infty} \frac{y_0 K}{y_0 + (K - y_0)e^{-rt}} = \lim_{t \to \infty} \frac{y_0 K}{y_0} = K$$

Thus we can conclude that the equilibrium solution $y(t) = K$ is asymptotically stable, while equilibrium solution $y(t) = 0$ is unstable.

The only way to guarantee solution remains near zero is to make $y_0 = 0$. 
Example 1: Pacific Halibut (1 of 2)

Let $y$ be biomass (in kg) of halibut population at time $t$, with $r = 0.71$/year and $K = 80.5 \times 10^6$ kg. If $y_0 = 0.25K$, find

(a) biomass 2 years later

(b) the time $\tau$ such that $y(\tau) = 0.75K$.

(a) For convenience, scale equation:

$$
\frac{y}{K} = \frac{y_0/K}{y_0/K + (1 - y_0/K)e^{-rt}}
$$

Then

$$
\frac{y(2)}{K} = \frac{0.25}{0.25 + 0.75e^{-(0.71)(2)}} \approx 0.5797
$$

and hence

$$
y(2) \approx 0.5797K \approx 46.7 \times 10^6 \text{ kg}
$$
Example 1: Pacific Halibut, Part (b) (2 of 2)

(b) Find time $\tau$ for which $y(\tau) = 0.75K$.

$$\frac{y}{K} = \frac{y_0/K}{y_0/K + (1 - y_0/K)e^{-rt}}$$

$$0.75 = \frac{y_0/K}{y_0/K + (1 - y_0/K)e^{-r\tau}}$$

$$0.75 \left[ \frac{y_0}{K} \left( 1 - \frac{y_0}{K} \right) e^{-r\tau} \right] = \frac{y_0}{K}$$

$$0.75 \frac{y_0}{K} + 0.75(1 - \frac{y_0}{K})e^{-r\tau} = \frac{y_0}{K}$$

$$e^{-r\tau} = \frac{0.25 y_0/K}{0.75(1 - y_0/K)} = \frac{y_0/K}{3(1 - y_0/K)}$$

$$\tau = \frac{-1}{0.71 \ln \left( \frac{0.25}{3(0.75)} \right)} \approx 3.095 \text{ years}$$
Critical Threshold Equation  (1 of 2)

Consider the following modification of the logistic ODE:

\[
\frac{dy}{dt} = -r \left(1 - \frac{y}{T}\right)y, \quad r > 0
\]

The graph of the right hand side \( f(y) \) is given below.
Critical Threshold Equation: Qualitative Analysis and Solution  (2 of 2)

Performing an analysis similar to that of the logistic case, we obtain a graph of solution curves shown below.

\( T \) is a **threshold value** for \( y_0 \), in that population dies off or grows unbounded, depending on which side of \( T \) the initial value \( y_0 \) is.

See also laminar flow discussion in text.

It can be shown that the solution to the threshold equation

\[
\frac{dy}{dt} = -r \left( 1 - \frac{y}{T} \right) y, \quad r > 0
\]

is

\[
y = \frac{y_0 T}{y_0 + (T - y_0) e^{rt}}
\]
Logistic Growth with a Threshold  (1 of 2)

In order to avoid unbounded growth for $y > T$ as in previous setting, consider the following modification of the logistic equation:

$$\frac{dy}{dt} = -r \left(1 - \frac{y}{T}\right) \left(1 - \frac{y}{K}\right) y, \quad r > 0 \text{ and } 0 < T < K$$

The graph of the right hand side $f(y)$ is given below.
Logistic Growth with a Threshold  (2 of 2)

Performing an analysis similar to that of the logistic case, we obtain a graph of solution curves shown below right.

- $T$ is threshold value for $y_0$, in that population dies off or grows towards $K$, depending on which side of $T$ $y_0$ is.
- $K$ is the carrying capacity level.
- Note: $y = 0$ and $y = K$ are stable equilibrium solutions, and $y = T$ is an unstable equilibrium solution.
