Lecture 12, MATH-57091 Probability and Statistics for High-School Teachers.

Artem Zvavitch

Department of Mathematical Sciences, Kent State University

November 19, 2014.

In lecture 11 we have done hypothesis testing when the only unknown parameter was the mean (and the variance is known).

In lecture 11 we have done hypothesis testing when the only unknown parameter was the mean (and the variance is known). But clearly, on practice (as we learned before) there are a lot of cases when the variance is also unknown. And this is the case we would like to study now!

In lecture 11 we have done hypothesis testing when the only unknown parameter was the mean (and the variance is known). But clearly, on practice (as we learned before) there are a lot of cases when the variance is also unknown. And this is the case we would like to study now!
Assume we have a sample of size n

$$X_1, X_2, \ldots, X_n$$

from a normal population having **unknown mean μ and unknown standard deviation σ**.

In lecture 11 we have done hypothesis testing when the only unknown parameter was the mean (and the variance is known). But clearly, on practice (as we learned before) there are a lot of cases when the variance is also unknown. And this is the case we would like to study now!
Assume we have a sample of size n

$$X_1, X_2, \dots, X_n$$

from a normal population having **unknown mean** μ **and unknown standard deviation** σ. Suppose that we are interesting using this data to test

$$H_0: \quad \mu = \mu_0 \quad \text{against the alternative} \quad H_1: \quad \mu \neq \mu_0.$$

In lecture 11 we have done hypothesis testing when the only unknown parameter was the mean (and the variance is known). But clearly, on practice (as we learned before) there are a lot of cases when the variance is also unknown. And this is the case we would like to study now!
Assume we have a sample of size n

$$X_1, X_2, \ldots, X_n$$

from a normal population having **unknown mean** μ **and unknown standard deviation** σ. Suppose that we are interesting using this data to test

$$H_0: \quad \mu = \mu_0 \quad \text{against the alternative} \quad H_1: \quad \mu \neq \mu_0.$$

As in Lecture 11, it is logical to reject H_0 if the point estimator (in this case $\bar{X}$) is far from μ_0, and the question is how to define "far".

In lecture 11 we have done hypothesis testing when the only unknown parameter was the mean (and the variance is known). But clearly, on practice (as we learned before) there are a lot of cases when the variance is also unknown. And this is the case we would like to study now!
Assume we have a sample of size n

$$X_1, X_2, \ldots, X_n$$

from a normal population having **unknown mean** μ **and unknown standard deviation** σ. Suppose that we are interesting using this data to test

$$H_0: \quad \mu = \mu_0 \quad \text{against the alternative} \quad H_1: \quad \mu \neq \mu_0.$$

As in Lecture 11, it is logical to reject H_0 if the point estimator (in this case $\bar{X}$) is far from μ_0, and the question is how to define "far". In the case of known standard deviation σ we agreed to reject H_0 depending on

$$\frac{\sqrt{n}(\bar{X} - \mu_0)}{\sigma}$$

In lecture 11 we have done hypothesis testing when the only unknown parameter was the mean (and the variance is known). But clearly, on practice (as we learned before) there are a lot of cases when the variance is also unknown. And this is the case we would like to study now!
Assume we have a sample of size n

$$X_1, X_2, \dots, X_n$$

from a normal population having **unknown mean** μ **and unknown standard deviation** σ. Suppose that we are interesting using this data to test

$$H_0: \quad \mu = \mu_0 \quad \text{against the alternative} \quad H_1: \quad \mu \neq \mu_0.$$

As in Lecture 11, it is logical to reject H_0 if the point estimator (in this case $\bar{X}$) is far from μ_0, and the question is how to define "far". In the case of known standard deviation σ we agreed to reject H_0 depending on

$$\frac{\sqrt{n}(\bar{X} - \mu_0)}{\sigma}$$

(i.e reject if absolute value of above is greater then $z_{\alpha/2}$).

In lecture 11 we have done hypothesis testing when the only unknown parameter was the mean (and the variance is known). But clearly, on practice (as we learned before) there are a lot of cases when the variance is also unknown. And this is the case we would like to study now!
Assume we have a sample of size n

$$X_1, X_2, \dots, X_n$$

from a normal population having **unknown mean** μ **and unknown standard deviation** σ. Suppose that we are interesting using this data to test

$$H_0: \quad \mu = \mu_0 \quad \text{against the alternative} \quad H_1: \quad \mu \neq \mu_0.$$

As in Lecture 11, it is logical to reject H_0 if the point estimator (in this case $\bar{X}$) is far from μ_0, and the question is how to define "far". In the case of known standard deviation σ we agreed to reject H_0 depending on

$$\frac{\sqrt{n}(\bar{X} - \mu_0)}{\sigma}$$

(i.e reject if absolute value of above is greater then $z_{\alpha/2}$). **BUT σ is unknown....**

So we will use the estimator!

So we will use the estimator! Consider the sample standard deviation:

$$S = \sqrt{\frac{\sum_{i=1}^{n}(X_i - \bar{X})^2}{n-1}}.$$

So we will use the estimator! Consider the sample standard deviation:

$$S = \sqrt{\frac{\sum_{i=1}^{n}(X_i - \bar{X})^2}{n-1}}.$$

We will use the test that will reject H_0 depending on value

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S}$$

So we will use the estimator! Consider the sample standard deviation:

$$S = \sqrt{\frac{\sum_{i=1}^{n}(X_i - \bar{X})^2}{n-1}}.$$

We will use the test that will reject H_0 depending on value

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S}$$

We need to determine how large $|T|$ needs to be to justify rejection at the level of significance α (i.e. probability of error of the first type - to reject something which is actually true).

So we will use the estimator! Consider the sample standard deviation:

$$S = \sqrt{\frac{\sum_{i=1}^{n}(X_i - \bar{X})^2}{n-1}}.$$

We will use the test that will reject H_0 depending on value

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S}$$

We need to determine how large $|T|$ needs to be to justify rejection at the level of significance α (i.e. probability of error of the first type - to reject something which is actually true). For this, we need to know its probability distribution of T **when** H_0 is true.

So we will use the estimator! Consider the sample standard deviation:

$$S = \sqrt{\frac{\sum_{i=1}^{n}(X_i - \bar{X})^2}{n-1}}.$$

We will use the test that will reject H_0 depending on value

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S}$$

We need to determine how large $|T|$ needs to be to justify rejection at the level of significance α (i.e. probability of error of the first type - to reject something which is actually true). For this, we need to know its probability distribution of T **when** H_0 is true. But we done it in Lecture 10 (Lecture 10.1, slides 17 and after) , indeed when $\mu = \mu_0$ we get that T has a t distribution with $n-1$ degrees of freedom.

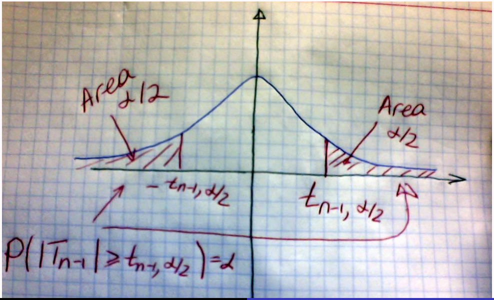
So we will use the estimator! Consider the sample standard deviation:

$$S = \sqrt{\frac{\sum_{i=1}^{n}(X_i - \bar{X})^2}{n-1}}.$$

We will use the test that will reject H_0 depending on value

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S}$$

We need to determine how large $|T|$ needs to be to justify rejection at the level of significance α (i.e. probability of error of the first type - to reject something which is actually true). For this, we need to know its probability distribution of T **when** H_0 is true. But we done it in Lecture 10 (Lecture 10.1, slides 17 and after) , indeed when $\mu = \mu_0$ we get that T has a t distribution with $n-1$ degrees of freedom. Using logic of lecture 11 we define $t_{n-1,\alpha/2}$ to be a number such that $P(|T| \geq t_{n-1,\alpha/2}) = \alpha$.



So here the plan: If we want to make significance-level-α test of

$$H_0: \quad \mu = \mu_0 \quad \text{against the alternative} \quad H_1: \quad \mu \neq \mu_0.$$

with σ unknown

So here the plan: If we want to make significance-level-α test of

$$H_0: \quad \mu = \mu_0 \quad \text{against the alternative} \quad H_1: \quad \mu \neq \mu_0.$$

with σ unknown we do **two-sided t test**

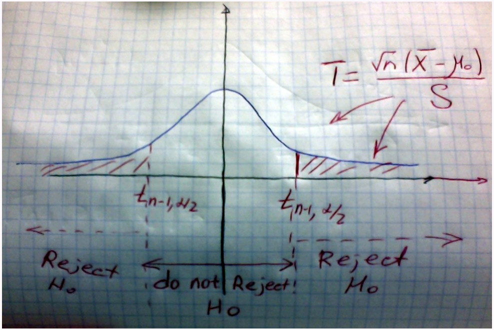
$$\begin{array}{ll} \text{Reject } H_0 & \text{if } |T| = \left| \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} \right| \geq t_{n-1,\alpha/2} \\ \text{Not Reject } H_0 & \text{otherwise.} \end{array}$$

So here the plan: If we want to make significance-level-α test of

$$H_0: \quad \mu = \mu_0 \quad \text{against the alternative} \quad H_1: \quad \mu \neq \mu_0.$$

with σ unknown we do **two-sided t test**

$$\begin{array}{ll} \text{Reject } H_0 & \text{if } |T| = \left| \frac{\sqrt{n}(\bar{X}-\mu_0)}{S} \right| \geq t_{n-1,\alpha/2} \\ \text{Not Reject } H_0 & \text{otherwise.} \end{array}$$



p value

Assume we have computed $T = \frac{\sqrt{n}(\bar{X}-\mu_0)}{S}$ as we agreed we will reject H_0 if

$$|T| = \left|\frac{\sqrt{n}(\bar{X}-\mu_0)}{S}\right| \geq t_{n-1,\alpha/2}.$$

p value

Assume we have computed $T = \frac{\sqrt{n}(\bar{X}-\mu_0)}{S}$ as we agreed we will reject H_0 if

$$|T| = \left|\frac{\sqrt{n}(\bar{X}-\mu_0)}{S}\right| \geq t_{n-1,\alpha/2}.$$

Clearly, our decision **depends on** α: as larger probability of error we allow (larger α) as greater $t_{n-1,\alpha/2}$ becomes and thus there is a greater chance to reject H_0.

Assume we have computed $T = \frac{\sqrt{n}(\bar{X}-\mu_0)}{S}$ as we agreed we will reject H_0 if

$$|T| = \left| \frac{\sqrt{n}(\bar{X}-\mu_0)}{S} \right| \geq t_{n-1,\alpha/2}.$$

Clearly, our decision **depends on** α: as larger probability of error we allow (larger α) as greater $t_{n-1,\alpha/2}$ becomes and thus there is a greater chance to reject H_0. From another point of view we will not reject H_0 when α is very small.

Assume we have computed $T = \frac{\sqrt{n}(\bar{X}-\mu_0)}{S}$ as we agreed we will reject H_0 if

$$|T| = \left| \frac{\sqrt{n}(\bar{X}-\mu_0)}{S} \right| \geq t_{n-1,\alpha/2}.$$

Clearly, our decision **depends on** α: as larger probability of error we allow (larger α) as greater $t_{n-1,\alpha/2}$ becomes and thus there is a greater chance to reject H_0. From another point of view we will not reject H_0 when α is very small. Thus it is logical to ask what is the minimal α for which we will be able to reject the error,

Assume we have computed $T = \frac{\sqrt{n}(\bar{X}-\mu_0)}{S}$ as we agreed we will reject H_0 if

$$|T| = \left| \frac{\sqrt{n}(\bar{X}-\mu_0)}{S} \right| \geq t_{n-1,\alpha/2}.$$

Clearly, our decision **depends on** α: as larger probability of error we allow (larger α) as greater $t_{n-1,\alpha/2}$ becomes and thus there is a greater chance to reject H_0. From another point of view we will not reject H_0 when α is very small. Thus it is logical to ask what is the minimal α for which we will be able to reject the error, i.e. α such that

$$\left| \frac{\sqrt{n}(\bar{X}-\mu_0)}{S} \right| = t_{n-1,\alpha/2}.$$

Assume we have computed $T = \frac{\sqrt{n}(\bar{X}-\mu_0)}{S}$ as we agreed we will reject H_0 if

$$|T| = \left|\frac{\sqrt{n}(\bar{X}-\mu_0)}{S}\right| \geq t_{n-1,\alpha/2}.$$

Clearly, our decision **depends on** α: as larger probability of error we allow (larger α) as greater $t_{n-1,\alpha/2}$ becomes and thus there is a greater chance to reject H_0. From another point of view we will not reject H_0 when α is very small. Thus it is logical to ask what is the minimal α for which we will be able to reject the error, i.e. α such that

$$\left|\frac{\sqrt{n}(\bar{X}-\mu_0)}{S}\right| = t_{n-1,\alpha/2}.$$

Or (formally):

Let the value of test statistics $\frac{\sqrt{n}(\bar{X}-\mu_0)}{S} = \nu$ then

$$p \text{ value } = P(|T_{n-1}| \geq |\nu|) = 2P(T_{n-1} \geq |\nu|)$$

where T_{n-1} is a t random variable with $n-1$ degrees of freedom.

Example

Among clinic's patients having high blood cholesterol levels, volunteers were recruited to test a new drug designed to reduce blood cholesterol. A group of 40 volunteers were given the drug for 60 days, and the changes in their blood cholesterol levels were noted. If the average change was a decrease of 6.8 with a sample standard deviation of 12.1, what conclusion can we draw? Use 5 percent level of significance.

Example

Among clinic's patients having high blood cholesterol levels, volunteers were recruited to test a new drug designed to reduce blood cholesterol. A group of 40 volunteers were given the drug for 60 days, and the changes in their blood cholesterol levels were noted. If the average change was a decrease of 6.8 with a sample standard deviation of 12.1, what conclusion can we draw? Use 5 percent level of significance.

Solution: Let us first test the hypothesis that any change in blood cholesterol level were purely due to chance.

Example

Among clinic's patients having high blood cholesterol levels, volunteers were recruited to test a new drug designed to reduce blood cholesterol. A group of 40 volunteers were given the drug for 60 days, and the changes in their blood cholesterol levels were noted. If the average change was a decrease of 6.8 with a sample standard deviation of 12.1, what conclusion can we draw? Use 5 percent level of significance.

Solution: Let us first test the hypothesis that any change in blood cholesterol level were purely due to chance. That is, let us use the data to test the null hypothesis

$$H_0: \quad \mu = 0 \quad \text{against the alternative} \quad H_1: \quad \mu \neq 0,$$

where μ is the mean decrease in cholesterol.

Example

Among clinic's patients having high blood cholesterol levels, volunteers were recruited to test a new drug designed to reduce blood cholesterol. A group of 40 volunteers were given the drug for 60 days, and the changes in their blood cholesterol levels were noted. If the average change was a decrease of 6.8 with a sample standard deviation of 12.1, what conclusion can we draw? Use 5 percent level of significance.

Solution: Let us first test the hypothesis that any change in blood cholesterol level were purely due to chance. That is, let us use the data to test the null hypothesis

$$H_0: \quad \mu = 0 \quad \text{against the alternative} \quad H_1: \quad \mu \neq 0,$$

where μ is the mean decrease in cholesterol. The value of the test statistic T is

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} = \frac{\sqrt{40}(6.8 - 0)}{12.1} = 3.554.$$

Example

Among clinic's patients having high blood cholesterol levels, volunteers were recruited to test a new drug designed to reduce blood cholesterol. A group of 40 volunteers were given the drug for 60 days, and the changes in their blood cholesterol levels were noted. If the average change was a decrease of 6.8 with a sample standard deviation of 12.1, what conclusion can we draw? Use 5 percent level of significance.

Solution: Let us first test the hypothesis that any change in blood cholesterol level were purely due to chance. That is, let us use the data to test the null hypothesis

$$H_0: \quad \mu = 0 \quad \text{against the alternative} \quad H_1: \quad \mu \neq 0,$$

where μ is the mean decrease in cholesterol. The value of the test statistic T is

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} = \frac{\sqrt{40}(6.8 - 0)}{12.1} = 3.554.$$

Using the table on the previous slide we get $t_{n-1,\alpha/2} = t_{39,0.025} = 2.023$ and the null hypothesis is rejected at 5 percent level of significance.

Example

Among clinic's patients having high blood cholesterol levels, volunteers were recruited to test a new drug designed to reduce blood cholesterol. A group of 40 volunteers were given the drug for 60 days, and the changes in their blood cholesterol levels were noted. If the average change was a decrease of 6.8 with a sample standard deviation of 12.1, what conclusion can we draw? Use 5 percent level of significance.

Solution: Let us first test the hypothesis that any change in blood cholesterol level were purely due to chance. That is, let us use the data to test the null hypothesis

$$H_0: \quad \mu = 0 \quad \text{against the alternative} \quad H_1: \quad \mu \neq 0,$$

where μ is the mean decrease in cholesterol. The value of the test statistic T is

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} = \frac{\sqrt{40}(6.8 - 0)}{12.1} = 3.554.$$

Using the table on the previous slide we get $t_{n-1,\alpha/2} = t_{39,0.025} = 2.023$ and the null hypothesis is rejected at 5 percent level of significance. In fact we may also compute p value:

Example

Among clinic's patients having high blood cholesterol levels, volunteers were recruited to test a new drug designed to reduce blood cholesterol. A group of 40 volunteers were given the drug for 60 days, and the changes in their blood cholesterol levels were noted. If the average change was a decrease of 6.8 with a sample standard deviation of 12.1, what conclusion can we draw? Use 5 percent level of significance.

Solution: Let us first test the hypothesis that any change in blood cholesterol level were purely due to chance. That is, let us use the data to test the null hypothesis

$$H_0: \quad \mu = 0 \quad \text{against the alternative} \quad H_1: \quad \mu \neq 0,$$

where μ is the mean decrease in cholesterol. The value of the test statistic T is

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} = \frac{\sqrt{40}(6.8 - 0)}{12.1} = 3.554.$$

Using the table on the previous slide we get $t_{n-1,\alpha/2} = t_{39,0.025} = 2.023$ and the null hypothesis is rejected at 5 percent level of significance. In fact we may also compute p value:

$$p \text{ value } = P(|T_{n-1}| \geq |\nu|) = 2P(T_{39} \geq 3.554) \approx 2 * 0.0005 = 0.001.$$

Example

Among clinic's patients having high blood cholesterol levels, volunteers were recruited to test a new drug designed to reduce blood cholesterol. A group of 40 volunteers were given the drug for 60 days, and the changes in their blood cholesterol levels were noted. If the average change was a decrease of 6.8 with a sample standard deviation of 12.1, what conclusion can we draw? Use 5 percent level of significance.

Solution: Let us first test the hypothesis that any change in blood cholesterol level were purely due to chance. That is, let us use the data to test the null hypothesis

$$H_0: \quad \mu = 0 \quad \text{against the alternative} \quad H_1: \quad \mu \neq 0,$$

where μ is the mean decrease in cholesterol. The value of the test statistic T is

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} = \frac{\sqrt{40}(6.8 - 0)}{12.1} = 3.554.$$

Using the table on the previous slide we get $t_{n-1,\alpha/2} = t_{39,0.025} = 2.023$ and the null hypothesis is rejected at 5 percent level of significance. In fact we may also compute p value:

$$p \text{ value } = P(|T_{n-1}| \geq |\nu|) = 2P(T_{39} \geq 3.554) \approx 2 * 0.0005 = 0.001.$$

So at any significance level greater then $1/10$ of the percent we will reject the hypothesis that the change in levels is due solely to chance.

Example

Among clinic's patients having high blood cholesterol levels, volunteers were recruited to test a new drug designed to reduce blood cholesterol. A group of 40 volunteers were given the drug for 60 days, and the changes in their blood cholesterol levels were noted. If the average change was a decrease of 6.8 with a sample standard deviation of 12.1, what conclusion can we draw? Use 5 percent level of significance.

Solution: Let us first test the hypothesis that any change in blood cholesterol level were purely due to chance. That is, let us use the data to test the null hypothesis

$$H_0: \quad \mu = 0 \quad \text{against the alternative} \quad H_1: \quad \mu \neq 0,$$

where μ is the mean decrease in cholesterol. The value of the test statistic T is

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} = \frac{\sqrt{40}(6.8 - 0)}{12.1} = 3.554.$$

Using the table on the previous slide we get $t_{n-1,\alpha/2} = t_{39,0.025} = 2.023$ and the null hypothesis is rejected at 5 percent level of significance. In fact we may also compute p value:

$$p \text{ value } = P(|T_{n-1}| \geq |\nu|) = 2P(T_{39} \geq 3.554) \approx 2 * 0.0005 = 0.001.$$

So at any significance level greater then $1/10$ of the percent we will reject the hypothesis that the change in levels is due solely to chance.
SPECIAL NOTE: we would not be justified at this point in concluding that the change in cholesterol levels are due to the specific drug!

Example

Historical data indicate that the mean acidity (pH) level of rain in certain industrial region in West Virginia is 5.2. To see whether there has been any recent change in this value, the acidity levels of 12 rainstorms over the past year have been measured, with the following results:

$$6.1, 6.4, 4.8, 5.8, 6.6, 5.3, 6.1, 4.4, 3.9, 6.8, 6.5, 6.3.$$

Do you think that this data strong enough, at the 5 percent level of significance, to conclude that the acidity level has changed from the historical data?

Example

Historical data indicate that the mean acidity (pH) level of rain in certain industrial region in West Virginia is 5.2. To see whether there has been any recent change in this value, the acidity levels of 12 rainstorms over the past year have been measured, with the following results:

$$6.1, 6.4, 4.8, 5.8, 6.6, 5.3, 6.1, 4.4, 3.9, 6.8, 6.5, 6.3.$$

Do you think that this data strong enough, at the 5 percent level of significance, to conclude that the acidity level has changed from the historical data?

Solution: We will test the hypothesis that acidity level have not changed:

$$H_0: \quad \mu = 5.2 \quad \text{against the alternative} \quad H_1: \quad \mu \neq 5.2.$$

Example

Historical data indicate that the mean acidity (pH) level of rain in certain industrial region in West Virginia is 5.2. To see whether there has been any recent change in this value, the acidity levels of 12 rainstorms over the past year have been measured, with the following results:

$$6.1, 6.4, 4.8, 5.8, 6.6, 5.3, 6.1, 4.4, 3.9, 6.8, 6.5, 6.3.$$

Do you think that this data strong enough, at the 5 percent level of significance, to conclude that the acidity level has changed from the historical data?

Solution: We will test the hypothesis that acidity level have not changed:

$$H_0: \quad \mu = 5.2 \quad \text{against the alternative} \quad H_1: \quad \mu \neq 5.2.$$

Using calculator, or computer we find out that $\bar{X} = 5.667$ and $S = 0.921$.

Example

Historical data indicate that the mean acidity (pH) level of rain in certain industrial region in West Virginia is 5.2. To see whether there has been any recent change in this value, the acidity levels of 12 rainstorms over the past year have been measured, with the following results:

$$6.1, 6.4, 4.8, 5.8, 6.6, 5.3, 6.1, 4.4, 3.9, 6.8, 6.5, 6.3.$$

Do you think that this data strong enough, at the 5 percent level of significance, to conclude that the acidity level has changed from the historical data?

Solution: We will test the hypothesis that acidity level have not changed:

$$H_0: \quad \mu = 5.2 \quad \text{against the alternative} \quad H_1: \quad \mu \neq 5.2.$$

Using calculator, or computer we find out that $\bar{X} = 5.667$ and $S = 0.921$. Thus, the value of test statistics is

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} = \frac{\sqrt{12}(5.667 - 5.2)}{0.921} = 1.76.$$

Example

Historical data indicate that the mean acidity (pH) level of rain in certain industrial region in West Virginia is 5.2. To see whether there has been any recent change in this value, the acidity levels of 12 rainstorms over the past year have been measured, with the following results:

$$6.1, 6.4, 4.8, 5.8, 6.6, 5.3, 6.1, 4.4, 3.9, 6.8, 6.5, 6.3.$$

Do you think that this data strong enough, at the 5 percent level of significance, to conclude that the acidity level has changed from the historical data?

Solution: We will test the hypothesis that acidity level have not changed:

$$H_0: \quad \mu = 5.2 \quad \text{against the alternative} \quad H_1: \quad \mu \neq 5.2.$$

Using calculator, or computer we find out that $\bar{X} = 5.667$ and $S = 0.921$. Thus, the value of test statistics is

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} = \frac{\sqrt{12}(5.667 - 5.2)}{0.921} = 1.76.$$

We use the table to find $t_{n-1,\alpha/2} = t_{11,0.025} = 2.201$,

Example

Historical data indicate that the mean acidity (pH) level of rain in certain industrial region in West Virginia is 5.2. To see whether there has been any recent change in this value, the acidity levels of 12 rainstorms over the past year have been measured, with the following results:

$$6.1, 6.4, 4.8, 5.8, 6.6, 5.3, 6.1, 4.4, 3.9, 6.8, 6.5, 6.3.$$

Do you think that this data strong enough, at the 5 percent level of significance, to conclude that the acidity level has changed from the historical data?

Solution: We will test the hypothesis that acidity level have not changed:

$$H_0: \quad \mu = 5.2 \quad \text{against the alternative} \quad H_1: \quad \mu \neq 5.2.$$

Using calculator, or computer we find out that $\bar{X} = 5.667$ and $S = 0.921$. Thus, the value of test statistics is

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} = \frac{\sqrt{12}(5.667 - 5.2)}{0.921} = 1.76.$$

We use the table to find $t_{n-1,\alpha/2} = t_{11,0.025} = 2.201$, thus the null hypothesis is not rejected at the 5 percent level of significance, and the data is not strong enough!

Example

Historical data indicate that the mean acidity (pH) level of rain in certain industrial region in West Virginia is 5.2. To see whether there has been any recent change in this value, the acidity levels of 12 rainstorms over the past year have been measured, with the following results:

$$6.1, 6.4, 4.8, 5.8, 6.6, 5.3, 6.1, 4.4, 3.9, 6.8, 6.5, 6.3.$$

Do you think that this data strong enough, at the 5 percent level of significance, to conclude that the acidity level has changed from the historical data?

Solution: We will test the hypothesis that acidity level have not changed:

$$H_0: \quad \mu = 5.2 \quad \text{against the alternative} \quad H_1: \quad \mu \neq 5.2.$$

Using calculator, or computer we find out that $\bar{X} = 5.667$ and $S = 0.921$. Thus, the value of test statistics is

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} = \frac{\sqrt{12}(5.667 - 5.2)}{0.921} = 1.76.$$

We use the table to find $t_{n-1,\alpha/2} = t_{11,0.025} = 2.201$, thus the null hypothesis is not rejected at the 5 percent level of significance, and the data is not strong enough! We can also compute the p value:

$$p \text{ value } = P(|T_{n-1}| \geq |\nu|) = 2P(T_{11} \geq 1.76) \approx 2 * 0.05 = 0.1$$

Example

Historical data indicate that the mean acidity (pH) level of rain in certain industrial region in West Virginia is 5.2. To see whether there has been any recent change in this value, the acidity levels of 12 rainstorms over the past year have been measured, with the following results:

$$6.1, 6.4, 4.8, 5.8, 6.6, 5.3, 6.1, 4.4, 3.9, 6.8, 6.5, 6.3.$$

Do you think that this data strong enough, at the 5 percent level of significance, to conclude that the acidity level has changed from the historical data?

Solution: We will test the hypothesis that acidity level have not changed:

$$H_0: \quad \mu = 5.2 \quad \text{against the alternative} \quad H_1: \quad \mu \neq 5.2.$$

Using calculator, or computer we find out that $\bar{X} = 5.667$ and $S = 0.921$. Thus, the value of test statistics is

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} = \frac{\sqrt{12}(5.667 - 5.2)}{0.921} = 1.76.$$

We use the table to find $t_{n-1,\alpha/2} = t_{11,0.025} = 2.201$, thus the null hypothesis is not rejected at the 5 percent level of significance, and the data is not strong enough! We can also compute the p value:

$$p \text{ value } = P(|T_{n-1}| \geq |\nu|) = 2P(T_{11} \geq 1.76) \approx 2 * 0.05 = 0.1$$

and thus null hypothesis is not rejected even at 9 percent level of significance.

One-sided tests

Absolutely the same ideology should be used for one sided test!

One-sided tests

Absolutely the same ideology should be used for one sided test! Before we were studying hypothesis of type $\mu = \mu_0$.

One-sided tests

Absolutely the same ideology should be used for one sided test! Before we were studying hypothesis of type $\mu = \mu_0$. Quite often we are interested to test

$$\begin{aligned} H_0 : &\quad \mu \leq \mu_0 \text{ against} \\ H_1 : &\quad \mu > \mu_0 \end{aligned}$$

Absolutely the same ideology should be used for one sided test! Before we were studying hypothesis of type $\mu = \mu_0$. Quite often we are interested to test

$$H_0 : \quad \mu \le \mu_0 \text{ against}$$
$$H_1 : \quad \mu > \mu_0$$

We will want to reject H_0 when the sample mean $\bar{X}$ is much larger than μ_0, it can be shown in exactly the same way as in two-sided case that the significance-level-α test is to

$$\text{Reject } H_0 : \quad \frac{\sqrt{n}}{S}(\bar{X} - \mu_0) \ge t_{n-1,\alpha}$$
$$\text{Not Reject } H_0 : \quad \frac{\sqrt{n}}{S}(\bar{X} - \mu_0) < t_{n-1,\alpha}.$$

Absolutely the same ideology should be used for one sided test! Before we were studying hypothesis of type $\mu = \mu_0$. Quite often we are interested to test

$$\begin{aligned} H_0: &\quad \mu \le \mu_0 \text{ against} \\ H_1: &\quad \mu > \mu_0 \end{aligned}$$

We will want to reject H_0 when the sample mean $\bar{X}$ is much larger than μ_0, it can be shown in exactly the same way as in two-sided case that the significance-level-α test is to

$$\begin{aligned} \text{Reject } H_0: &\quad \frac{\sqrt{n}}{S}(\bar{X} - \mu_0) \ge t_{n-1,\alpha} \\ \text{Not Reject } H_0: &\quad \frac{\sqrt{n}}{S}(\bar{X} - \mu_0) < t_{n-1,\alpha}. \end{aligned}$$

We can also compute the p value (i.e.the smallest significance level at which the data lead to rejection of H_0).

Absolutely the same ideology should be used for one sided test! Before we were studying hypothesis of type $\mu = \mu_0$. Quite often we are interested to test

$$\begin{array}{ll} H_0: & \mu \le \mu_0 \text{ against} \\ H_1: & \mu > \mu_0 \end{array}$$

We will want to reject H_0 when the sample mean $\bar{X}$ is much larger than μ_0, it can be shown in exactly the same way as in two-sided case that the significance-level-α test is to

$$\begin{array}{ll} \text{Reject } H_0: & \frac{\sqrt{n}}{S}(\bar{X} - \mu_0) \ge t_{n-1,\alpha} \\ \text{Not Reject } H_0: & \frac{\sqrt{n}}{S}(\bar{X} - \mu_0) < t_{n-1,\alpha}. \end{array}$$

We can also compute the p value (i.e.the smallest significance level at which the data lead to rejection of H_0). For this, we first compute the statistical data $\sqrt{n}(\bar{X} - \mu_0)/S$ (assume it takes value ν),

Absolutely the same ideology should be used for one sided test! Before we were studying hypothesis of type $\mu = \mu_0$. Quite often we are interested to test

$$\begin{aligned} H_0: &\quad \mu \le \mu_0 \text{ against} \\ H_1: &\quad \mu > \mu_0 \end{aligned}$$

We will want to reject H_0 when the sample mean $\bar{X}$ is much larger than μ_0, it can be shown in exactly the same way as in two-sided case that the significance-level-α test is to

$$\begin{aligned} \text{Reject } H_0: &\quad \frac{\sqrt{n}}{S}(\bar{X} - \mu_0) \ge t_{n-1,\alpha} \\ \text{Not Reject } H_0: &\quad \frac{\sqrt{n}}{S}(\bar{X} - \mu_0) < t_{n-1,\alpha}. \end{aligned}$$

We can also compute the p value (i.e.the smallest significance level at which the data lead to rejection of H_0). For this, we first compute the statistical data $\sqrt{n}(\bar{X} - \mu_0)/S$ (assume it takes value ν), then the p value is equal to

$$p \text{ value} = P(T_{n-1} \ge \nu),$$

where T_{n-1} is a t random variable with $n-1$ degrees of freedom

Absolutely the same ideology should be used for one sided test! Before we were studying hypothesis of type $\mu = \mu_0$. Quite often we are interested to test

$$\begin{array}{ll} H_0: & \mu \le \mu_0 \text{ against} \\ H_1: & \mu > \mu_0 \end{array}$$

We will want to reject H_0 when the sample mean $\bar{X}$ is much larger than μ_0, it can be shown in exactly the same way as in two-sided case that the significance-level-α test is to

$$\begin{array}{ll} \text{Reject } H_0: & \frac{\sqrt{n}}{S}(\bar{X} - \mu_0) \ge t_{n-1,\alpha} \\ \text{Not Reject } H_0: & \frac{\sqrt{n}}{S}(\bar{X} - \mu_0) < t_{n-1,\alpha}. \end{array}$$

We can also compute the p value (i.e.the smallest significance level at which the data lead to rejection of H_0). For this, we first compute the statistical data $\sqrt{n}(\bar{X} - \mu_0)/S$ (assume it takes value ν), then the p value is equal to

$$p \text{ value} = P(T_{n-1} \ge \nu),$$

where T_{n-1} is a t random variable with $n-1$ degrees of freedom The null hypothesis is then rejected at any significance level greater than or equal to the value p.

Summary for the Hypothesis test concerning the mean μ of a Normal Population with Unknown Variance σ^2.

Summary for the Hypothesis test concerning the mean μ of a Normal Population with Unknown Variance σ^2.

Let $X_1, \dots, X_n$ are a sample data and $\bar{X} = \frac{1}{n}\sum_{i=1}^{n} X_i$ and $S^2 = \frac{1}{n-1}\sum_{i=1}^{n}(X_i - \bar{X})^2$.

Summary for the Hypothesis test concerning the mean μ of a Normal Population with Unknown Variance σ^2.

Let $X_1, \dots, X_n$ are a sample data and $\bar{X} = \frac{1}{n}\sum_{i=1}^{n} X_i$ and $S^2 = \frac{1}{n-1}\sum_{i=1}^{n}(X_i - \bar{X})^2$. Then

H_0 :	H_1	Test Statistics (TS)	Significance-level-α test	p Value if TS$= \nu$
$\mu = \mu_0$	$\mu \neq \mu_0$	$\frac{\sqrt{n}}{S}(\bar{X} - \mu_0)$	Reject H_0 if $\lvert TS\rvert \geq t_{n-1,\alpha/2}$. Do not reject H_0 otherwise	$2P(T_{n-1} \geq \lvert\nu\rvert)$
$\mu \leq \mu_0$	$\mu > \mu_0$	$\frac{\sqrt{n}}{S}(\bar{X} - \mu_0)$	Reject H_0 if $TS \geq t_{n-1,\alpha}$. Do not reject H_0 otherwise	$P(T_{n-1} \geq \nu)$
$\mu \geq \mu_0$	$\mu < \mu_0$	$\frac{\sqrt{n}}{S}(\bar{X} - \mu_0)$	Reject H_0 if $TS \leq -t_{n-1,\alpha}$. Do not reject H_0 otherwise	$P(T_{n-1} \leq \nu)$

Example

The manufacturer of new fiberglass tire claims that the average life of a set of its tires is at least 50 thousand miles. To verify this claim, a sample of 8 sets of tires was chosen and tested. If the resulting values of the sample mean and sample standard deviation were, respectively 47.2 and 3.1 thousand miles, test the manufacturer's claim.

Example

The manufacturer of new fiberglass tire claims that the average life of a set of its tires is at least 50 thousand miles. To verify this claim, a sample of 8 sets of tires was chosen and tested. If the resulting values of the sample mean and sample standard deviation were, respectively 47.2 and 3.1 thousand miles, test the manufacturer's claim.

Solution: We will test the hypothesis that acidity level have not changed:

$$H_0: \quad \mu \geq 50 \quad \text{against the alternative} \quad H_1: \quad \mu < 50.$$

Example

The manufacturer of new fiberglass tire claims that the average life of a set of its tires is at least 50 thousand miles. To verify this claim, a sample of 8 sets of tires was chosen and tested. If the resulting values of the sample mean and sample standard deviation were, respectively 47.2 and 3.1 thousand miles, test the manufacturer's claim.

Solution: We will test the hypothesis that acidity level have not changed:

$$H_0: \quad \mu \geq 50 \quad \text{against the alternative} \quad H_1: \quad \mu < 50.$$

Then the value of the test statistics

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} = \frac{\sqrt{8}(47.2 - 50)}{3.1} = -2.55$$

Example

The manufacturer of new fiberglass tire claims that the average life of a set of its tires is at least 50 thousand miles. To verify this claim, a sample of 8 sets of tires was chosen and tested. If the resulting values of the sample mean and sample standard deviation were, respectively 47.2 and 3.1 thousand miles, test the manufacturer's claim.

Solution: We will test the hypothesis that acidity level have not changed:

$$H_0: \quad \mu \geq 50 \quad \text{against the alternative} \quad H_1: \quad \mu < 50.$$

Then the value of the test statistics

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} = \frac{\sqrt{8}(47.2 - 50)}{3.1} = -2.55$$

Since $t_{7,0.05} = 1.895$ and the test tell us to reject H_0 when T less than or equal to $-t_{7,0.05}$, it follows that H_0 is rejected at 5 percent level of significance.

Example

The manufacturer of new fiberglass tire claims that the average life of a set of its tires is at least 50 thousand miles. To verify this claim, a sample of 8 sets of tires was chosen and tested. If the resulting values of the sample mean and sample standard deviation were, respectively 47.2 and 3.1 thousand miles, test the manufacturer's claim.

Solution: We will test the hypothesis that acidity level have not changed:

$$H_0: \quad \mu \geq 50 \quad \text{against the alternative} \quad H_1: \quad \mu < 50.$$

Then the value of the test statistics

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} = \frac{\sqrt{8}(47.2 - 50)}{3.1} = -2.55$$

Since $t_{7,0.05} = 1.895$ and the test tell us to reject H_0 when T less than or equal to $-t_{7,0.05}$, it follows that H_0 is rejected at 5 percent level of significance. On the other hand, since $t_{7,0.01} = 2.998$, H_0 would not be rejected at 1 percent level.

Example

The manufacturer of new fiberglass tire claims that the average life of a set of its tires is at least 50 thousand miles. To verify this claim, a sample of 8 sets of tires was chosen and tested. If the resulting values of the sample mean and sample standard deviation were, respectively 47.2 and 3.1 thousand miles, test the manufacturer's claim.

Solution: We will test the hypothesis that acidity level have not changed:

$$H_0: \quad \mu \geq 50 \quad \text{against the alternative} \quad H_1: \quad \mu < 50.$$

Then the value of the test statistics

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S} = \frac{\sqrt{8}(47.2 - 50)}{3.1} = -2.55$$

Since $t_{7,0.05} = 1.895$ and the test tell us to reject H_0 when T less than or equal to $-t_{7,0.05}$, it follows that H_0 is rejected at 5 percent level of significance. On the other hand, since $t_{7,0.01} = 2.998$, H_0 would not be rejected at 1 percent level. Playing with tables we get that p value is about 0.02, illustrating that the data strongly indicate that the manufacturer claim is invalid!
